

Hamming-distance RadViz projection: organoid_shGFP real cells (by predicted.id, 50% HDR contours)

vs. GEMM's fixed archetype anchors

Full projection (true scale)
dashed box = region magnified at right

Zoomed inset -- same data, magnified

Note: each contour is the smallest region containing 50% of that organoid predicted.id group's estimated probability mass (2D Gaussian KDE over the group's Hamming-distance projection), evaluated on a shared grid so contours are directly comparable across groups. Groups with <20 cells are shown as raw points instead, since a KDE from that few cells would be unreliable. Hexagon vertices + the 2 circles are GEMM's own fitted archetype average states, colored to match their same-named organoid group where one exists (Secretory and nonNE2 have no organoid predicted.id counterpart here, so keep distinct colors). See `plot_radviz_archetype_projection.py` for the full projection method and the confirmed Generalist_NE centering divergence from the original reference figure.
